Conclusions

Main steps:

- Identifying the **relevant** sources of uncertainty;
- [Performing (Local (i.e., around nominal values) or Global) Sensitivity Analysis for Parameter Selection];
- Creating a physics-based non-deterministic characterization of inadequacies;
- [Constructing surrogate models];
- Calibrating Parameters and hyperparameters;
- Performing the **reductions** of the downstream **models** (when **possible**);
- Forward propagating of the (approximated) posterior distribution;
- Analyzing the Qols' sensitivity;
- Conducting predictive assessment;
- Proposing improvements.
